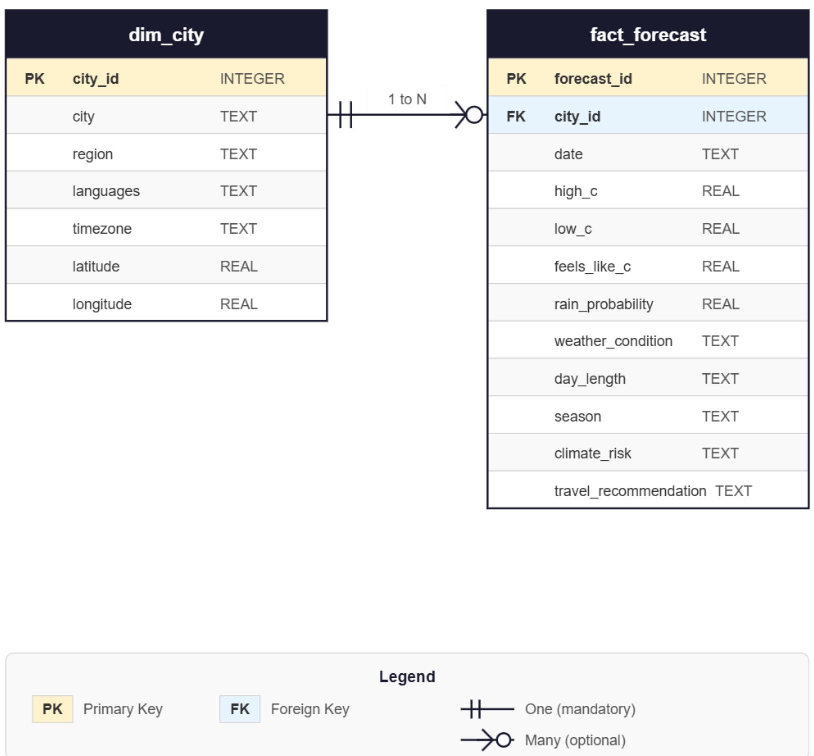
Entity Relationship Diagram



Relationship Summary

The diagram above shows two entities connected by a one to many relationship. The dim_city table is the parent entity. The fact_forecast table is the child entity. One city in dim_city can have many forecast records in fact_forecast, linked through the city_id foreign key.

Key Constraints

- city_id in dim_city is the Primary Key (PK). It uniquely identifies each city.
- city_id in fact_forecast is the Foreign Key (FK). It references dim_city.city_id to link each forecast to its city.

- forecast_id in fact_forecast is the Primary Key (PK). It uniquely identifies each forecast record.
- A unique constraint on city_id and date prevents duplicate forecast records for the same city on the same day.

Cardinality

One row in dim_city corresponds to exactly 7 rows in fact_forecast, one for each day in the 7 day forecast window. With 10 cities the total is 10 rows in dim_city and 70 rows in fact_forecast.
